

**PYRROLOBENZODIAZEPINES**

The present invention relates to pyrrolobenzodiazepines (PBDs),  
and in particular pyrrolobenzodiazepines useful in the synthesis  
5 of dimeric compounds.

**Background to the invention**

Some pyrrolobenzodiazepines (PBDs) have the ability to recognise  
and bond to specific sequences of DNA; the preferred sequence is  
10 PuGpu. The first PBD antitumour antibiotic, anthramycin, was  
discovered in 1965 (Leimgruber, *et al.*, *J. Am. Chem. Soc.*, **87**,  
5793-5795 (1965); Leimgruber, *et al.*, *J. Am. Chem. Soc.*, **87**, 5791-  
5793 (1965)). Since then, a number of naturally occurring PBDs  
have been reported, and over 10 synthetic routes have been  
15 developed to a variety of analogues (Thurston, *et al.*, *Chem. Rev.*  
**1994**, 433-465 (1994)). Family members include abbeymycin  
(Hochlowski, *et al.*, *J. Antibiotics*, **40**, 145-148 (1987)),  
chicamycin (Konishi, *et al.*, *J. Antibiotics*, **37**, 200-206 (1984)),  
DC-81 (Japanese Patent 58-180 487; Thurston, *et al.*, *Chem. Brit.*,  
20 **26**, 767-772 (1990); Bose, *et al.*, *Tetrahedron*, **48**, 751-758  
(1992)), mazethramycin (Kuminoto, *et al.*, *J. Antibiotics*, **33**, 665-  
667 (1980)), neothramycins A and B (Takeuchi, *et al.*, *J.*  
*Antibiotics*, **29**, 93-96 (1976)), porothramycin (Tsunakawa, *et al.*,  
*J. Antibiotics*, **41**, 1366-1373 (1988)), prothracarcin (Shimizu, *et*  
25 *al.*, *J. Antibiotics*, **29**, 2492-2503 (1982); Langley and Thurston, *J.*  
*Org. Chem.*, **52**, 91-97 (1987)), sibanomicin (DC-102) (Hara, *et al.*,  
*J. Antibiotics*, **41**, 702-704 (1988); Itoh, *et al.*, *J. Antibiotics*,  
**41**, 1281-1284 (1988)), sibiromycin (Leber, *et al.*, *J. Am. Chem.*  
*Soc.*, **110**, 2992-2993 (1988)) and tomamycin (Arima, *et al.*, *J.*  
30 *Antibiotics*, **25**, 437-444 (1972)). PBDs are of the general  
structure:

They differ in the number, type and position of substituents, in both their aromatic A rings and pyrrolo C rings, and in the degree of saturation of the C ring. In the B-ring there is either an imine (N=C), a carbinolamine (NH-CH(OH)), or a carbinolamine methyl ether (NH-CH(OMe)) at the N10-C11 position which is the electrophilic centre responsible for alkylating DNA. All of the known natural products have an (S)-configuration at the chiral C11a position which provides them with a right-handed twist when viewed from the C ring towards the A ring. This gives them the appropriate three-dimensional shape for isohelicity with the minor groove of B-form DNA, leading to a snug fit at the binding site (Kohn, In *Antibiotics III*. Springer-Verlag, New York, pp. 3-11 (1975); Hurley and Needham-VanDevanter, *Acc. Chem. Res.*, **19**, 230-237 (1986)). Their ability to form an adduct in the minor groove, enables them to interfere with DNA processing, hence their use as antitumour agents.

The present inventors have previously disclosed, in WO 00/12508, dimeric cytotoxic PBD compounds substituted at the C2 position, for example:

The synthesis of these compounds was achieved by formation of the dimeric backbone comprising the assembled A and C rings linked through the A ring by the diether linking chain. The N10 position was then protected with an Alloc group before a ring closure reaction to form the B ring and subsequent deprotection to give the product. The key stage in this synthesis is described as the

ring closure to form the B ring which occurs after the linking of the two A rings with the diether chain.

Using this route, to synthesise a number of dimers having the same monomer groups but different bridging groups require the synthesis of each compound from scratch, i.e. the synthesis route is not able to readily produce a diverse collection of PBD dimers, where the diversity is in the dimer bridge.

## Definitions

### *Carbamate-based nitrogen protecting groups*

Carbamate-based nitrogen protecting groups are well known in the  
 art, and have the following structure:

wherein  $R^{10}$  is R as defined above. A large number of suitable  
 groups are described on pages 503 to 549 of Greene, T.W. and Wuts,  
 G.M., *Protective Groups in Organic Synthesis*, 3<sup>rd</sup> Edition, John  
 Wiley & Sons, Inc., 1999, which is incorporated herein by  
 reference.

Particularly preferred protecting groups include Alloc, Troc,  
 Fmoc, CBz, Teoc, BOC, Doc, Hoc, TcBOC, 1-Adoc and 2-Adoc.

Also suitable for use in the present invention are nitrogen protecting group which can be removed *in vivo* (e.g. enzymatically, using light) as described in WO 00/12507, which is incorporated herein by reference. Examples of these protecting groups include:

, which is nitroreductase labile (e.g. using ADEPT/GDEPT);

and

, which are photolabile; and

which is glutathione labile (e.g. using NPEPT).

#### *Oxygen protecting groups*

Oxygen protecting groups are well known in the art. A large number of suitable groups are described on pages 23 to 200 of Greene, T.W. and Wuts, G.M., *Protective Groups in Organic Synthesis*, 3<sup>rd</sup> Edition, John Wiley & Sons, Inc., 1999, which is incorporated herein by reference.

Classes of particular interest include silyl ethers, methyl ethers, alkyl ethers, benzyl ethers, esters, benzoates, carbonates, and sulfonates.

Preferred oxygen protecting groups include TBS, THP for the C11 oxygen atom, and benzyl ether for the C7 or C8 oxygen atom (where present).

As mentioned above the oxygen protecting group  $R^{14}$  should be orthogonal to the oxygen protecting group  $R^{11}$ . Protecting groups which are orthogonal to one another may each be removed using reagents or conditions which do not remove the other protecting group.

It may also be preferred that any protecting groups used during the synthesis and use of compounds of formula **I** are orthogonal to one another. However, it is often not necessary, but may be desirable, for the carbamate-based nitrogen protecting group and  $R^{11}$  to be orthogonal to one another, depending on whether the compound of formula **IIIa** or **IIIb** is to be used with the nitrogen protecting group in place.

#### *Proliferative Diseases*

One of ordinary skill in the art is readily able to determine whether or not a candidate compound treats a proliferative condition for any particular cell type. For example, assays which may conveniently be used to assess the activity offered by a particular compound are described in the examples below.

30

The term "proliferative disease" pertains to an unwanted or uncontrolled cellular proliferation of excessive or abnormal cells

35

which is undesired, such as, neoplastic or hyperplastic growth, whether *in vitro* or *in vivo*.

Examples of proliferative conditions include, but are not limited to, benign, pre-malignant, and malignant cellular proliferation, including but not limited to, neoplasms and tumours (e.g. histocytoma, glioma, astrocyoma, osteoma), cancers (e.g. lung cancer, small cell lung cancer, gastrointestinal cancer, bowel cancer, colon cancer, breast carcinoma, ovarian carcinoma, prostate cancer, testicular cancer, liver cancer, kidney cancer, bladder cancer, pancreas cancer, brain cancer, sarcoma, osteosarcoma, Kaposi's sarcoma, melanoma), leukemias, psoriasis, bone diseases, fibroproliferative disorders (e.g. of connective tissues), and atherosclerosis.

Any type of cell may be treated, including but not limited to, lung, gastrointestinal (including, e.g. bowel, colon), breast (mammary), ovarian, prostate, liver (hepatic), kidney (renal), bladder, pancreas, brain, and skin.

#### Methods of Treatment

As described above, the present invention provide the use of a compound of formula **IIIa** or **IIIb** in a method of therapy. Also provided is a method of treatment, comprising administering to a subject in need of treatment a therapeutically-effective amount of a compound of formula **IIIa** or **IIIb**, preferably in the form of a pharmaceutical composition, which is the third aspect of the present invention. The term "therapeutically effective amount" is an amount sufficient to show benefit to a patient. Such benefit may be at least amelioration of at least one symptom. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of what is being treated. Prescription of treatment, e.g. decisions on dosage, is within the responsibility of general practitioners and other medical doctors.

A compound may be administered alone or in combination with other treatments, either simultaneously or sequentially dependent upon the condition to be treated. Examples of treatments and therapies include, but are not limited to, chemotherapy (the administration of active agents, including, e.g. drugs; surgery; and radiation therapy. If the compound of formula **IIIa** or **IIIb** bears a carbamate-based nitrogen protecting group which may be removed *in vivo*, then the methods of treatment described in WO 00/12507 (ADEPT, GDEPT and PDT) may be used.

Pharmaceutical compositions according to the present invention, and for use in accordance with the present invention, may comprise, in addition to the active ingredient, i.e. a compound of formula **IIIa** or **IIIb**, a pharmaceutically acceptable excipient, carrier, buffer, stabiliser or other materials well known to those skilled in the art. Such materials should be non-toxic and should not interfere with the efficacy of the active ingredient. The precise nature of the carrier or other material will depend on the route of administration, which may be oral, or by injection, e.g. cutaneous, subcutaneous, or intravenous.

Pharmaceutical compositions for oral administration may be in tablet, capsule, powder or liquid form. A tablet may comprise a solid carrier or an adjuvant. Liquid pharmaceutical compositions generally comprise a liquid carrier such as water, petroleum, animal or vegetable oils, mineral oil or synthetic oil. Physiological saline solution, dextrose or other saccharide solution or glycols such as ethylene glycol, propylene glycol or polyethylene glycol may be included. A capsule may comprise a solid carrier such as a gelatin.

For intravenous, cutaneous or subcutaneous injection, or injection at the site of affliction, the active ingredient will be in the form of a parenterally acceptable aqueous solution which is pyrogen-free and has suitable pH, isotonicity and stability. Those of relevant skill in the art are well able to prepare

suitable solutions using, for example, isotonic vehicles such as Sodium Chloride Injection, Ringer's Injection, Lactated Ringer's Injection. Preservatives, stabilisers, buffers, antioxidants and/or other additives may be included, as required.

#### Includes Other Forms

Unless otherwise specified, included in the above are the well known ionic, salt, solvate, and protected forms of these substituents. For example, a reference to carboxylic acid ( $-\text{COOH}$ ) also includes the anionic (carboxylate) form ( $-\text{COO}^-$ ), a salt or solvate thereof, as well as conventional protected forms. Similarly, a reference to an amino group includes the protonated form ( $-\text{N}^+\text{HR}^1\text{R}^2$ ), a salt or solvate of the amino group, for example, a hydrochloride salt, as well as conventional protected forms of an amino group. Similarly, a reference to a hydroxyl group also includes the anionic form ( $-\text{O}^-$ ), a salt or solvate thereof, as well as conventional protected forms.

#### Isomers, Salts and Solvates

Certain compounds may exist in one or more particular geometric, optical, enantiomeric, diastereomeric, epimeric, atropic, stereoisomeric, tautomeric, conformational, or anomeric forms, including but not limited to, cis- and trans-forms; E- and Z-forms; c-, t-, and r- forms; endo- and exo-forms; R-, S-, and meso-forms; D- and L-forms; d- and l-forms; (+) and (-) forms; keto-, enol-, and enolate-forms; syn- and anti-forms; synclinal- and anticlinal-forms;  $\alpha$ - and  $\beta$ -forms; axial and equatorial forms; boat-, chair-, twist-, envelope-, and halfchair-forms; and combinations thereof, hereinafter collectively referred to as "isomers" (or "isomeric forms").

25

30

Preferably compounds of the present invention have the following stereochemistry at the C11 position:

Note that, except as discussed below for tautomeric forms, specifically excluded from the term "isomers", as used herein, are structural (or constitutional) isomers (i.e. isomers which differ in the connections between atoms rather than merely by the position of atoms in space). For example, a reference to a methoxy group,  $-OCH_3$ , is not to be construed as a reference to its structural isomer, a hydroxymethyl group,  $-CH_2OH$ . Similarly, a reference to ortho-chlorophenyl is not to be construed as a reference to its structural isomer, meta-chlorophenyl. However, a reference to a class of structures may well include structurally isomeric forms falling within that class (e.g.  $C_{1-7}$  alkyl includes n-propyl and iso-propyl; butyl includes n-, iso-, sec-, and tert-butyl; methoxyphenyl includes ortho-, meta-, and para-methoxyphenyl).

The above exclusion does not pertain to tautomeric forms, for example, keto-, enol-, and enolate-forms, as in, for example, the following tautomeric pairs: keto/enol (illustrated below), imine/enamine, amide/imino alcohol, amidine/amidine, nitroso/oxime, thioketone/enethiol, N-nitroso/hydroxyazo, and nitro/aci-nitro.

Note that specifically included in the term "isomer" are compounds with one or more isotopic substitutions. For example, H may be in any isotopic form, including  $^1\text{H}$ ,  $^2\text{H}$  (D), and  $^3\text{H}$  (T); C may be in any isotopic form, including  $^{12}\text{C}$ ,  $^{13}\text{C}$ , and  $^{14}\text{C}$ ; O may be in any isotopic form, including  $^{16}\text{O}$  and  $^{18}\text{O}$ ; and the like.

Unless otherwise specified, a reference to a particular compound includes all such isomeric forms, including (wholly or partially) racemic and other mixtures thereof. Methods for the preparation (e.g. asymmetric synthesis) and separation (e.g. fractional crystallisation and chromatographic means) of such isomeric forms are either known in the art or are readily obtained by adapting the methods taught herein, or known methods, in a known manner.

Unless otherwise specified, a reference to a particular compound also includes ionic, salt, solvate, and protected forms of thereof, for example, as discussed below.

It may be convenient or desirable to prepare, purify, and/or handle a corresponding salt of the active compound, for example, a pharmaceutically-acceptable salt. Examples of pharmaceutically acceptable salts are discussed in Berge, et al., *J. Pharm. Sci.*, **66**, 1-19 (1977).

For example, if the compound is anionic, or has a functional group which may be anionic (e.g. -COOH may be -COO<sup>-</sup>), then a salt may be formed with a suitable cation. Examples of suitable inorganic cations include, but are not limited to, alkali metal ions such as Na<sup>+</sup> and K<sup>+</sup>, alkaline earth cations such as Ca<sup>2+</sup> and Mg<sup>2+</sup>, and other cations such as Al<sup>3+</sup>. Examples of suitable organic cations include, but are not limited to, ammonium ion (i.e. NH<sub>4</sub><sup>+</sup>) and substituted ammonium ions (e.g. NH<sub>3</sub>R<sup>+</sup>, NH<sub>2</sub>R<sub>2</sub><sup>+</sup>, NHR<sub>3</sub><sup>+</sup>, NR<sub>4</sub><sup>+</sup>). Examples of some suitable substituted ammonium ions are those derived from: ethylamine, diethylamine, dicyclohexylamine, triethylamine, butylamine, ethylenediamine, ethanolamine, diethanolamine, piperazine, benzylamine, phenylbenzylamine, choline, meglumine, and tromethamine, as well as amino acids, such as lysine and arginine. An example of a common quaternary ammonium ion is N(CH<sub>3</sub>)<sub>4</sub><sup>+</sup>.

If the compound is cationic, or has a functional group which may be cationic (e.g.  $\text{-NH}_2$  may be  $\text{-NH}_3^+$ ), then a salt may be formed with a suitable anion. Examples of suitable inorganic anions include, but are not limited to, those derived from the following inorganic acids: hydrochloric, hydrobromic, hydroiodic, sulfuric, sulfurous, nitric, nitrous, phosphoric, and phosphorous.

Examples of suitable organic anions include, but are not limited to, those derived from the following organic acids:

2-acetyoxybenzoic, acetic, ascorbic, aspartic, benzoic, camphorsulfonic, cinnamic, citric, edetic, ethanedisulfonic, ethanesulfonic, fumaric, glucheptonic, gluconic, glutamic, glycolic, hydroxymaleic, hydroxynaphthalene carboxylic, isethionic, lactic, lactobionic, lauric, maleic, malic, methanesulfonic, mucic, oleic, oxalic, palmitic, pamoic, pantothenic, phenylacetic, phenylsulfonic, propionic, pyruvic, salicylic, stearic, succinic, sulfanilic, tartaric, toluenesulfonic, and valeric. Examples of suitable polymeric organic anions include, but are not limited to, those derived from the following polymeric acids: tannic acid, carboxymethyl cellulose.

A particular salt form of interest can be formed from compounds of formula **IIIa** and **IIIb**, where  $\text{R}^{10}$  and  $\text{R}^{15}$  form an imine bond, by reacting said compound with a bisulphite salt to form a bisulphite derivative of the PBD. These compounds can be represented as:

where M and M' are independently monovalent pharmaceutically acceptable cations, or together form a divalent pharmaceutically acceptable cation, and the other groups are as previously defined.

5

It may be convenient or desirable to prepare, purify, and/or handle a corresponding solvate of the active compound. The term "solvate" is used herein in the conventional sense to refer to a complex of solute (e.g. active compound, salt of active compound) and solvent. If the solvent is water, the solvate may be conveniently referred to as a hydrate, for example, a mono-

10

Solvates of particular relevance to the present invention are those where the solvent adds across the imine bond of the PBD moiety, which is illustrated below where the solvent is water or an alcohol ( $R^B\text{OH}$ , where  $R^B$  is an ether substituent as described above):

15

20

These forms can be called the carbinolamine and carbinolamine ether forms of the PBD. The balance of these equilibria depend on

the conditions in which the compounds are found, as well as the nature of the moiety itself.

In general any nucleophilic solvent is capable of forming such solvates as illustrated above for hydroxylic solvents. Other nucleophilic solvents include thiols and amines.

These solvates may be isolated in solid form, for example, by lyophilisation.

#### General synthetic routes

The synthesis of PBD compounds is extensively discussed in WO 00/12508, which discussion is incorporated herein by reference.

As discussed in that patent application, a key step in a preferred route to PBDs is a cyclisation to produce the B-ring, involving generation of an aldehyde (or functional equivalent thereof) at what will be the 11-position, and attack thereon by the Pro-N10-nitrogen:

wherein the substituents are as defined in the second aspect of the invention and  $R^{12}$  and  $R^{13}$  are either  $OR^{14}$  and  $R^A$  respectively or  $R^A$  and  $OR^{14}$  respectively i.e. the protected hydroxyl group may be at either the C7 or C8 position with the other position being  $R^A$ . The "masked aldehyde" -CPQ may be an acetal or thioacetal, in which case the cyclisation involves unmasking. Alternatively, it may be an alcohol -CHOH, in which case the reaction involves oxidation, e.g. by means of TPAP, TEMPO or DMSO (Swern oxidation).

The masked aldehyde compound can be produced by condensing a corresponding 2,4-substituted pyrrolidine with a 2-nitrobenzoic acid:

5 The nitro group can then be reduced to -NH<sub>2</sub> and protected by reaction with a suitable agent, e.g. a chloroformate, which provides the removable nitrogen protecting group in the compound of formula IV.

10 A process involving the oxidation-cyclization procedure is illustrated in scheme 1 (an alternative type of cyclisation will be described later with reference to scheme 2).

Scheme 1

Exposure of the alcohol (B) (in which the Pro-N10-nitrogen is generally protected as carbamate) to tetrapropylammonium perruthenate (TPAP)/N-methylmorpholine N-oxide (NMO) over A4  
5 sieves results in oxidation accompanied by spontaneous B-ring closure to afford the desired product **IV**. The TPAP/NMO oxidation procedure is found to be particularly convenient for small scale reactions while the use of DMSO-based oxidation methods, particularly Swern oxidation, proves superior for larger scale  
10 work (e.g. > 1 g). A particularly preferred oxidising agent is (diacetoxyiodo)benzene (1.1 eq) and TEMPO (0.1 eq) dissolved in CH<sub>2</sub>Cl<sub>2</sub>.

The uncyclized alcohol (B) may be prepared by the reaction of a  
15 nitrogen protection reagent of formula D, which is preferably a chloroformate or acid chloride, to a solution of the amino alcohol C, generally in solution, generally in the presence of a base such as pyridine (preferably 2 equivalents) at a moderate temperature (e.g. at 0°C). Under these conditions little or no O-acylation is  
20 usually observed.

The key amino alcohol C may be prepared by reduction of the corresponding nitro compound E, by choosing a method which will leave the rest of the molecule intact. Treatment of E with tin  
25 (II) chloride in a suitable solvent, e.g. refluxing methanol, generally affords, after the removal of the tin salts, the desired product in high yield.

Exposure of E to hydrazine/Raney nickel avoids the production of  
30 tin salts and may result in a higher yield of C, although this method is less compatible with the range of possible C and A-ring substituents. For instance, if there is C-ring unsaturation (either in the ring itself, or in R<sub>2</sub> or R<sub>3</sub>), this technique may be unsuitable.

The nitro compound of formula E may be prepared by coupling the appropriate o-nitrobenzoyl chloride to a compound of formula F, e.g. in the presence of  $K_2CO_3$  at  $-25^\circ C$  under a  $N_2$  atmosphere. Compounds of formula F can be readily prepared, for example by  
5 olefination of the ketone derived from L-trans-hydroxy proline. The ketone intermediate can also be exploited by conversion to the enol triflate for use in palladium mediated coupling reactions.

The o-nitrobenzoyl chloride is synthesised from the o-nitrobenzoic  
10 acid (or alkyl ester after hydrolysis) of formula G, which itself is prepared from the vanillic acid (or alkyl ester) derivative H. Many of these are commercially available and some are disclosed in Althuis, T.H. and Hess, H.J., *J. Medicinal Chem.*, **20(1)**, 146-266 (1977).

## Alternative Cyclisation (Scheme 2)

Scheme 2

5 In scheme 1, the final or penultimate step was an oxidative cyclisation. An alternative, using thioacetal coupling, is shown in scheme 2. Mercury-mediated unmasking causes cyclisation to the protected PBD compound **IV**.

10 The thioacetal compound may be prepared as shown in scheme 2: the thioacetal protected C-ring [prepared via a literature method: Langley, D.R. & Thurston, D.E., *J. Organic Chemistry*, 52, 91-97 (1987)] is coupled to the o-nitrobenzoic acid (or alkyl ester after hydrolysis) (G) using a literature procedure. The resulting  
15 nitro compound cannot be reduced by hydrogenation, because of the

thioacetal group, so the tin(II) chloride method is used to afford the amine. This is then N-protected, e.g., by reaction with a chloroformate or acid chloride, such as 2,2,2-trichloroethylchloroformate.

Acetal-containing C-rings can be used as an alternative in this type of route with deprotection involving other methods, including the use of acidic conditions.

#### Alternative routes to PBDs

Alternative methods of synthesising N10 protected PBDs are disclosed in co-pending application PCT/GB2004/003873 (filed 10 September 2004) which claims priority from GB0321295.8 (filed 11 September 2003), which describes the use of isocyanate intermediates.

#### Formation of compounds **IIIa** and **IIIb** (Scheme 3)

Scheme 3

Formation of the protected compound **IIIb** dimer from compound **Ib** is illustrated, however, protected compound **IIIa** is formed in an analogous manner with compound **Ia** as the starting material.

The PBD dimer compound **IIIa** or **IIIb** may be synthesized by dimerisation of compounds of formula **Ia** or **Ib** respectively following deprotection of the OH group at either the C7 or C8 position. The synthesis route illustrated in scheme 3 shows compounds when the dimer linkage is of the formula  $-O-(CH_2)_n-O-$ .

The protected dimer **IIIa** or **IIIb** may be formed from compounds of formula **Ia** or **Ib** respectively through reaction with a disubstituted linking chain. The linking chain is preferably of the general form Y-R''-Y' where R'' is as previously defined and Y and Y' are groups which can be reacted with an alcohol to form an ether linkage. Y and Y' are preferably independently selected from I, Br, Cl, OH, mesylate or tosylate. In a preferred aspect, Y and Y' are the same. In a preferred aspect Y and Y' are both iodo- groups.

Where Y and/or Y' is I, Br, Cl, mesylate or tosylate, the Y-R''-Y' reactant is coupled to the compound of formula **Ia** or **Ib** by a simple elimination reaction with Y and Y' as leaving groups. For example where the linking chain is -O-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-O-, the compound of formula **Ia** or **Ib** is reacted with 1,3-diiodopropane in the presence of K<sub>2</sub>CO<sub>3</sub>. Generally, where the linking chain is a straight chain alkyl ether of the form -O-(CH<sub>2</sub>)<sub>n</sub>-O-, the compound of formula **Ia** or **Ib** is preferably reacted with the corresponding 1,n-diiodoalkane.

Where Y and/or Y' is OH, the Y-R''-Y' reactant is coupled to the compound of formula **Ia** or **Ib** under Mitsunobu conditions.

It is important that the OH protecting group at C11 in formula **Ia** or **Ib** is orthogonal to the OH protecting group at C7 and/or C8. This allows the C7 and/or C8 protection to be removed to give the free alcohol to allow dimerisation whilst the C11 OH group remains protected and therefore unreactive under the dimerisation conditions.

Following dimerisation, the imine bond in the compound of formula **IIIb-prot** can be deprotected by standard methods to yield the unprotected compound **IIIb** (which may be in its carbinolamine or carboinolamine ether form, depending on the solvents used). For example if R<sup>10</sup> is Alloc, then the deprotection is carried using palladium to remove the N10 protecting group, followed by the

elimination of water. If  $R^{10}$  is Troc, then the deprotection is carried out using a Cd/Pb couple to yield the compound of formula **IIIb**.

5 Compound **IIIa** may be formed in an analogous manner via deprotection of the protected imine.

10 If the nitrogen protecting group ( $R^{10}$ ) is such that the desired end product still contains it, e.g. if it is removable *in vivo*, then the C11 deprotected forms of compounds of formula **IIIa** or **IIIb** may be synthesised by removal of the oxygen protecting groups under suitable conditions to leave the  $R^{10}$  group in unaffected.

15 The above described methods are suited to the synthesis of dimers where both the PBD monomers have the same substituent pattern. One method of synthesising a dimer where the substituent pattern of the two PBD monomers is not the same involves protecting one end of the compound Y- $R''$ -Y' (or using an already protected compound), coupling a PBD monomer to the unprotected end, 20 deprotecting the other end and coupling a different PBD monomer to the free end. This route is shown in scheme 4.

Scheme 4

25 Where YProt, is a protected version, or precursor to Y'. If Y' is protected then the protecting group used should be orthogonal to those on the rest of the molecule, in particular,  $R^{10}$  and  $R^{11}$ . One

example of this route, would be to have Y as -OH and YProt as -O-benzyl. The first monomer could be joined by Mitsunobu coupling, the benzyl hydroxy deprotected, and then the free hydroxy coupled to the second monomer by a further Mitsunobu reaction.

5

*Formation of Compound of formula Ia or Ib*

Following cyclisation to form the B-ring, the C11-alcohol **IV** is then preferably protected, by conventional means to provide **II**.

10

For example, if  $R^{11}$  is THP, the protection can take place by reacting **IV** with dihydropyran (DHP) and catalytic *p*-toluene sulfonic acid. Cleavage of the C7 or C8-protecting group from **II** then provides the corresponding C7 or C8 alcohol. For example, where the C7 or C8 protecting group ( $R^{12}$  or  $R^{13}$ ) is a benzyl ether, this deprotection may be performed by reaction with  $H_2$  catalysed by

15

palladium on carbon.

This protection at the C11 position and deprotection of the C7 or C8 alcohol allows subsequent reaction of selectively the C7 or C8 alcohol position, for example to form the dimer compound **IIIa** or **IIIb** leaving the C11 position unaffected.

20

1-(3-dimethylaminopropyl)-3-ethylcarbodiimide (EDCI) (6.33 g, 33.0 mmol, 1.0 equiv) was added to a stirred solution of the acid **1** (10 g, 33.0 mol, 1.0 equiv) in anhydrous DCM (300 mL) under a nitrogen atmosphere at 0°C. After stirring for 10 minutes the mixture was treated with HOBt (4.46 g, 33.0 mmol, 1.0 equiv) and few drops of DMF and the resulting mixture was allowed to warm to room temperature and stirred for 2 h. The mixture was again cooled down to 0°C and treated with dropwise with a solution of pyrrolidinemethanol (5 g, 49.50 mmol, 1.5 equiv) in anhydrous DCM (100 mL). A solution of the ester **19** (3.8 g, 8.83 mmol, 1.0 equiv.) in THF (100 mL) was cooled to 0 °C and treated with  $\text{LiBH}_4$  (0.29 g, 13.25 mmol, 1.5 equiv.) in portions. After stirring for 30 min at 0 °C, the reaction mixture was allowed to warm to room temperature and stirred under a nitrogen atmosphere for 4 h at which time TLC ( $\text{SiO}_2$ , EtOAc) revealed complete consumption of ester **19**. The mixture was cooled to 0 °C again and water (100 mL) was carefully added followed by 1N HCl (250 mL) which provoked vigorous effervescence. After evaporation of the THF *in vacuo*, the mixture was neutralised to pH 7 with 1N NaOH. The aqueous solution was then extracted with EtOAc (4 x 70mL), the combined organic layers washed with brine (50 mL), dried ( $\text{MgSO}_4$ ), filtered and evaporated *in vacuo* to furnished the pure diol **20** (3.2 g, 7.96 mmol, 90%), which was used in the subsequent reaction without further

The mixture was extracted with chloroform (3 x 20 mL) and the organic layer was washed with water (20 mL), brine (20 mL), dried (MgSO<sub>4</sub>) and filtered. The excess solvent was removed under reduced pressure to give the crude product, which was subjected to flash column chromatography (SiO<sub>2</sub>, 2% methanol-chloroform). Removal of excess eluent under reduced pressure without heating afforded the final product **29c** (34 mg, 0.052 mmol, 61%) as a solid: [α]<sub>D</sub><sup>26</sup> = +309° (*c* = 0.31, CHCl<sub>3</sub>); <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz): δ 1.31-1.39 (m, 8H, 15-H, 16-H), 1.40-1.51 (m, 4H, 14-H), 1.80-1.93 (m, 4H, 13-H), 2.89-3.10 (m, 2H, 1-H), 3.06-3.19 (m, 2H, 1-H), 3.81-3.95 (m, 8H, 11a-H, 7-OMe), 3.98-4.11 (m, 4H, 12-H), 4.28 (s, 4H, 3-H), 5.16-5.18 (m, 4H, 2a-H), 6.80 (s, 2H, 9-H), 7.49 (s, 2H, 6-H), 7.66 (d, 2H, *J* = 4.56 Hz, 11-H); <sup>13</sup>C NMR (CDCl<sub>3</sub>, 100 MHz): δ 25.8, 28.8, 29.2, 29.4, 35.2, 51.3, 53.8, 56.2, 69.0, 109.3, 110.4, 111.4, 119.5, 140.7, 141.7, 151.1, 162.4, 164.8; IR (neat): 2933, 1599, 1506, 1464, 1429, 1380, 1262,

**Example 27 - Determination of DNA Cross-Linking ability and in vitro Cytotoxicity**

*(a) DNA Cross-linking*

The extent of DNA cross-linking induced by each PBD dimer was determined using the electrophoretic assay method of Hartley, et al. (Hartley, J. A., Berardini, M. D., and Souhami, R. L. (1991) *Anal. Biochem.* 193, 131-134) based on the principle that, following complete denaturation of linear pBR322 DNA (~4,300 bp) to the single-stranded (SS) form, an interstrand cross-link results in renaturation to double-stranded (DS) in a neutral gel.

Closed-circular DNA was linearized with HindIII, then dephosphorylated and finally 5'-singly end-labelled using [ $\gamma^{32}\text{P}$ ]-ATP and polynucleotide kinase. Reactions containing 30-40 ng of DNA and the test compound were carried out in aqueous TEOA (25 mM triethanolamine, 1mM EDTA, pH 7.2) buffer at 37°C in a final volume of 50  $\mu\text{l}$  for 2 hours. Reactions were terminated by addition of an equal volume of stop solution (0.6 M NaOAc, 20 mM EDTA, 100  $\mu\text{g}/\text{ml}$  tRNA) followed by precipitation with ethanol. Following centrifugation, the supernatant was discarded and the pellet dried by lyophilization. Samples were re-suspended in 10  $\mu\text{l}$  of strand separation buffer (30% DMSO, 1 mM EDTA, 0.04% bromophenol blue and 0.04% xylene cyanol) and denatured by heating to 90°C for 2.5 min, followed by immersion in an ice/water bath. Control non-denatured samples were re-suspended in 10  $\mu\text{l}$  of non-denaturing buffer solution (0.6% sucrose, 0.04% bromophenol blue in aqueous TAE buffer [40 mM Tris, 20 mM acetic acid, 2 mM EDTA, pH 8.1]) and loaded directly onto the gel for comparison.

Electrophoresis was carried out for 14-16 h at 40 V using a 0.8% submerged agarose gel (20  $\times$  25  $\times$  0.5 cm) in TAE buffer. Gels were dried under vacuum for 2 hour at 80°C onto one layer each of

Whatman 3MM and DE8I filter papers using a BioRad 583 gel dryer. Autoradiographs were obtained after exposure of Hyperfilm-MP film (Amersham plc, U.K.) to the dried gel for either 4 hour with a screen (or over night, without a screen, to obtain a sharper image). Film bands were quantitated using a BioRad GS-670 imaging laser densitometer. Percentage cross-linking was calculated by measuring the total DNA in each lane (summed density for the double-stranded [DS] and single-stranded [SS] bands) relative to the amount of cross-linked DNA (density of DS band alone). A dose-response curve was derived by plotting drug concentration against the determined percentage level of cross-linked DNA which was then analysed to determine the concentration of test compound that results in 50% cross-linked plasmid DNA (XL<sub>50</sub>).

*(b) In vitro cytotoxicity*

(i) K562 cells

K562 human chronic myeloid leukaemia cells were maintained in RPMI 1640 medium supplemented with 10% fetal calf serum and 2 mM glutamine at 37°C in a humidified atmosphere containing 5% CO<sub>2</sub> and were incubated with a specified dose of drug for 1 hour or 96 hours at 37°C in the dark. The incubation was terminated by centrifugation (5 min, 300 g) and the cells were washed once with drug-free medium. Following the appropriate drug treatment, the cells were transferred to 96-well microtiter plates (10<sup>4</sup> cells per well, 8 wells per sample). Plates were then kept in the dark at 37°C in a humidified atmosphere containing 5% CO<sub>2</sub>. The assay is based on the ability of viable cells to reduce a yellow soluble tetrazolium salt, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT, Aldrich-Sigma), to an insoluble purple formazan precipitate. Following incubation of the plates for 4 days (to allow control cells to increase in number by approximately 10 fold), 20 µL of MTT solution (5 mg/mL in phosphate-buffered saline) was added to each well and the plates further incubated for 5 hours. The plates were then centrifuged for 5 minutes at 300 g and the bulk of the medium pipetted from the cell pellet leaving 10-20 µL per well. DMSO (200 µL) was

added to each well and the samples agitated to ensure complete mixing. The optical density was then read at a wavelength of 550 nm on a Titertek Multiscan ELISA plate reader, and a dose-response curve was constructed. For each curve, an IC<sub>50</sub> value was read as the dose required to reduce the final optical density to 50% of the control value.

(ii) NCI 60 cell screen

The National Cancer Institute (NCI), Bethesda, Maryland, USA has available an *in vitro* cytotoxicity screen which consists of approximately 60 human tumour cell lines against which compounds are tested at a minimum of five concentrations each differing 10-fold. A 48 hour continuous exposure protocol is used, where cell viability or growth is estimated with an SRB protein assay.

The test compounds were evaluated against approximately 60 human tumour cell lines. The NCI screening procedures were described in detail by Monks and co-workers (Monks, A *et al.*, Journal of the National Cancer Institute, 1991, 83, 757). Briefly, cell suspensions were diluted according to the particular cell type and the expected target cell density (5000-40,000 cells per well based on cell growth characteristics), and added by pipette (100 µL) into 96-well microtitre plates. The cells were allowed a preincubation period of 24 hours at 37°C for stabilisation. Dilutions at twice the intended test concentration were added at time zero in 100 µL aliquots to the wells. The test compounds were evaluated at five 10-fold dilutions (10<sup>-4</sup>, 10<sup>-5</sup>, 10<sup>-6</sup>, 10<sup>-7</sup> and 10<sup>-8</sup> µM). The test compounds were incubated for 48 hours in 5% CO<sub>2</sub> atmosphere and 100% humidity. The cells were then assayed using the sulphorhodamine B assay. A plate reader was used to read the optical densities and a microcomputer processed the readings into GI<sub>50</sub> values (in Moles), which is the dosage required to limit cell growth to 50%.
